## **Application: System Specification and Relations**

Relations are useful for modelling systems and components because we often do not know the exact function.

- Consider a digital thermometer which reports temperature in whole degrees.
  - \* An ideal model of the behavour would be a function from  $\mathbb R$  to  $\mathbb N.$  For example

 $f(x) = \lfloor x + 0.5 \rfloor$ 

- \* However, in real life, sensors have only finite precision and finite operating ranges.
- \* Suppose the thermometer is always right to within  $0.6^{\circ}$

dom(R) = [-50, +200], rng $(R) = \mathbb{N}$  $xRn \text{ iff } x - 0.6 \le n \le x + 0.6$  Discrete Math. for Engineering, 2003. Applications Slide Set 6

\* Often inputs and outputs are functions of time. We might specify a thermometer with up to a 1 second lag by  $\operatorname{dom}(R) = (\mathbb{R} \rightarrow [-50, +200]), \quad \operatorname{rng}(R) = (\mathbb{R} \rightarrow \mathbb{N})$ 

$$xRn \text{ iff } \forall t \in \mathbb{R},$$

$$\exists t' \in \mathbb{R}, t-1 \le t' \le t$$
  
 
$$\land x(t') - 0.6 \le n(t) \le x(t') + 0.4$$

This is a relation relating two functions of time, where time is in seconds.

- \* If an actual thermometer behaves "better" than this specification then the actual system built will not be worse than the the system analysed using the specification.
- "Better" means the set of behaviours is a subset.
  E.g. a thermometer that is better, might obey the model

 $dom(R) = (\mathbb{R} \to [-50, +200]), \quad rng(R) = (\mathbb{R} \to \mathbb{N})$  $xRn \text{ iff } \forall t \in \mathbb{R},$ 

 $\exists t' \in \mathbb{R}, t - 0.5 \le t' \le t \\ \land x(t') - 0.55 \le n(t) \le x(t') + 0.55$

## **Relations for systems**

We can often describe a system in terms of relations

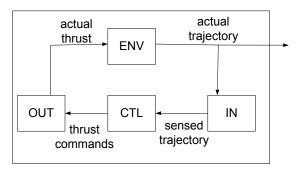

- *IN*: relates actual values in the environment to their sensed values
- *CTL*: relates sensed values to commands to actuators. This relation often is implemented in software.
- *OUT*: relates commands to actuators to the actual effect on the environment.
- ENV: describes how the environment behaves.

## Example

A rocket with various thrusters that can be either on or off.

The set of trajectories possible is

 $S = \{x \mid x(\textit{ENV} \circ \textit{OUT} \circ \textit{CTL} \circ \textit{IN})x\}$  If the requirement is specified as a set of allowable trajectories, R, then we must design the system so that  $S \subset R$
